FPro Class (0 = minimally processed, 3 = ultra-processed)

I prefer the second plot because it clearly highlights one of the key insights I found in the data: how food prices vary across processing levels and stores. I was particularly interested in understanding whether more processed foods are cheaper, and how this relationship differs between stores. This plot focuses on price across the different FPro classes, making it easier to compare trends directly. I chose to display medians as lines and interquartile ranges as shaded regions so that the viewer can quickly understand both the central tendency and the variability of prices. The line plot effectively shows overall trends, while the shaded regions provide additional context and prevent overreliance on the median alone. One important takeaway is that Whole Foods and Walmart show little overlap in their price ranges across most processing levels, suggesting that price is influenced more by the store itself than by how processed the food is.
